

CASE STUDY

Hoof Injury, Patient: VF Blood Brothers

Case presentation: On June 6, 2018,

a Long yearling Quarter Horse race horse kicked a weak beam of a stall and tore his left front hoof as he was pulling back. The horse was treated with antibiotics and casted for 2 weeks. The injury persisted and showed sign of infection.

On June 25, 2018, a 3.0 cc of RenoVō® allograft was implanted at the discretion of the veterinarian around the lesion and distributed subcutaneously around the wound edges.

On July 3, 2018,

only one week following the implantation of RenoVō®, the infection resolved, and the wound was re-epithelizing and had significantly decreased in size. Standard wound dressing, with bandage changes was performed as needed by the owner at the recommendation of the attending veterinarian.

On August 15, 2018,

six weeks later, the wound was healed, and the hoof wall and sole were growing back.

On February 21, 2019,

eight months following the RenoVō® implantation, the hoof injury was completely resolved. The horse had grown back a strong and healthy hoof. VF Blood Brothers has been back to racing again and has won multiples races.
